Introduction to Alkanes in Organic Chemistry

Alkanes are a fundamental class of hydrocarbons characterized by single bonds between carbon atoms. They are saturated hydrocarbons, meaning they contain the maximum number of hydrogen atoms possible for a given number of carbons. Understanding alkanes is crucial because they serve as the building blocks for more complex organic molecules.

What Are Alkanes?

Alkanes follow the general formula CnH2n+2, where 'n' is the number of carbon atoms. Examples include methane (CH4), ethane (C2H6), propane (C3H8), and butane (C4H10).

Properties of Alkanes

- Physical State: Typically gases or liquids at room temperature, becoming solids with increasing molecular weight.
- Boiling and Melting Points: Increase with molecular size due to greater London dispersion forces.
- Solubility: Insoluble in water but soluble in nonpolar solvents.
- Reactivity: Generally less reactive due to strong C?H and C?C bonds; mainly undergo substitution reactions.

Introduction to Alkanes

Alkanes, also known as saturated hydrocarbons, are organic compounds composed entirely of carbon and hydrogen atoms, linked exclusively by single covalent bonds. Their general formula is C?H??+?, indicating that for each number of carbon atoms, there are twice as many hydrogen atoms plus two.

Why Focus on Alkanes?

Understanding alkanes is essential because:

- They form the basis of all hydrocarbons.
- They are the simplest type of organic compounds, making them ideal starting points.
- Many natural resources, such as natural gas and petroleum, consist largely of alkanes.
- Their reactions and properties are fundamental to organic chemistry.

Structure and Nomenclature of Alkanes

Structural Features

- Tetrahedral Geometry: Carbon atoms in alkanes are sp^3 hybridized, resulting in a tetrahedral shape.
- Bond Angles: The bond angles are approximately 109.5°, which is characteristic of tetrahedral arrangements.
- Isomerism: As the number of carbon atoms increases, the number of possible structural isomers increases exponentially.

Nomenclature Rules (IUPAC)

Understanding how to name alkanes is vital. The nomenclature is systematic, based on the number

of carbon atoms:

- Identify the Longest Chain: The main chain is the longest continuous carbon chain.
- Number the Chain: Assign numbers to the carbon atoms, starting from the end nearest a substituent.
- Name the Substituents: Alkyl groups (e.g., methyl, ethyl) are named as substituents.
- Combine Names: The substituents' names are prefixed to the main chain, with their positions indicated by numbers.

Common Alkane Names

Number of Carbons	Alkane Name	Formula	Isomers
1	Methane	CH?	1
2	Ethane	C?H?	1
3	Propane	C?H?	1
4	Butane	C?H??	2
5	Pentane	C?H??	3
6	Hexane	C?H??	5

Physical Properties of Alkanes

Alkanes exhibit several characteristic physical properties:

- Boiling and Melting Points: Increase with molecular weight due to van der Waals forces.
- Solubility: Insoluble in water but soluble in organic solvents.
- Density: Less dense than water.
- Flammability: Highly combustible, producing carbon dioxide and water upon complete combustion.

Understanding these properties helps in practical applications such as fuel use and storage.

Reactivity of Alkanes

Alkanes are characterized by their relatively low reactivity, primarily due to the stability of their C?C and C?H single bonds. However, they do undergo specific types of reactions:

Types of Reactions

- Combustion:

Complete combustion produces carbon dioxide and water; incomplete combustion yields carbon monoxide or soot.

- Substitution Reactions (Halogenation):

In the presence of UV light, alkanes react with halogens (Cl?, Br?) to form haloalkanes.

- Cracking:

Larger alkanes can be broken down into smaller alkanes and alkenes in the presence of heat and catalysts.

Mechanisms of Reactions

Free Radical Substitution (Halogenation)

This is the main reaction for alkanes with halogens. The process involves three steps:

- Initiation: Formation of free radicals from halogen molecules under UV light.
- Propagation: Chain reactions where radicals react to produce new radicals.
- Termination: Radicals combine to form stable molecules, ending the chain.

Example: Chlorination of Methane

CH? + Cl? ? CH?Cl + HCl

The process yields chloromethane and hydrogen chloride, with the possibility of further substitution leading to di- and trichloromethane.

Important Concepts in Chapter 10 (Alkanes)

Isomerism in Alkanes

As the number of carbons increases, so does the variety of structural isomers. For instance, butane (C?H??) has two isomers: n-butane and isobutane (methylpropane).

Stereoisomerism

Alkanes generally do not exhibit stereoisomerism due to their free rotation around sigma bonds, but their derivatives (like substituted alkanes) may.

Sources of Alkanes

- Natural sources like natural gas and petroleum.
- Laboratory synthesis via cracking and other processes.

Key Laboratory Tests and Observations

Combustion Test

- Procedure: Burn a small sample of the alkane.
- Observation: Produces a carbon dioxide and water vapor, indicating a hydrocarbon.

Bromine Water Test (for Unsaturation)
